

1. Which NoSQL type would you use and why?

I would use a Key-Value Store for the player table.

This is the simplest NoSQL type because each player can be stored using their id as the key and their information as the value. Since the player table is small and does not require joins, a key-value store allows very fast lookups when retrieving a player's data.

2. Example of one record in that format

Key: "player:2544"

Value:

```
{  
  "id": "2544",  
  "full_name": "LeBron James",  
  "first_name": "LeBron",  
  "last_name": "James",  
  "is_active": 1  
}
```

3. What do you gain and what do you lose?

Gains:

Extremely fast lookups using the key

Very simple structure

Easy to implement and scale

Losses:

Cannot perform complex queries (like searching by last name easily)

No relationships between data

Less flexible for analytics compared to SQL
